Along with environmental adaptations, population genetics is another way to explain human variation. In

all organisms, the foremost means of achieving variation is through genetic mutation, specifically point mutation. Point mutations occur when a single nucleotide base is added, deleted, or replaced.

Genetic variation refers to differences among the genomes of members of the same species. A genome is all the hereditary information—all the genes—of

an organism. For instance,
the human genome contains
somewhere between twenty and
twenty-five thousand genes.

Even today, researchers are

still discovering new types of variants within human genomes. Human genomic variation is particularly important because a very small set of these variants are linked to differences in various physical traits:

Perhaps the most widely
cited statistic about human
genetic diversity is that
any two humans differ, on

average, at about 1 in 1,000 DNA base pairs (0.1%). Human genetic diversity is substantially lower than that of many other species, including our nearest evolutionary relative, the chimpanzee. Genetic

Human genetic variation is
the genetic differences in

Variation identification is the process of identifying genetic variations from DNA sequence data. 45 Usually variation identification can be done by comparing a newly

Access Free Human Variation A Genetic

sequenced human genome with
the reference human genome
and identifying candidate
sites at which one or more
samples differ from the
reference sequence. 46

Several tools for
identifying variations, such

as CRISP, GATK, and
SAMtools, are available. 47,
