Surface Impedance Boundary Conditions

Surface Impedance Boundary Conditions is perhaps the first effort to formalize the concept of SIBC or to extend it to higher orders by providing a comprehensive, consistent, and thorough approach to the subject. The product of nearly 12 years of research on surface impedance, this book takes the mystery out of the largely overlooked SIBC.

Surface impedance boundary conditions can be developed in a number of ways. The best known surface impedance is due to Leontovich whose surface impedance is no more than the wave impedance in the conductor [2,3] and since that is based on plane wave representation it is suitable for flat or locally flat surfaces.

The Dirichlet boundary condition (1.2.31) |S = 0 appears, e.g. for complex amplitude pressure in acoustics, when the surface material has a very low acoustic impedance compared to the acoustic impedance of the carrier medium (c2 c1). In this case the surface is called sound soft.

Abstract: When a surface impedance boundary condition is implemented in a numerical formulation, it must be represented in terms of the state variables of that formulation. The usual practice is to derive high order surface impedance boundary conditions, which take into account the curvature of the conductor surface, and express them as relations between tangential components of the electric ...

Summary. It is shown how the exact electromagnetic boundary conditions at the surface of a material of large refractive index can be approximated to yield the usual impedance or Leontovich boundary conditions. These conditions relate the tangential components of the electric and magnetic fields (or the normal components and their normal derivatives) via a surface impedance which is a function only of the electromagnetic properties of the material.

surface impedance boundary condition that is applicable for a single frequency and a dispersive surface impedance boundary condition that is applicable over a large frequency bandwidth and range of conductivities. The dispersive surface impedance includes frequency variations which results in a time domain boundary condition involving a convolution.

Surface impedance boundary conditions are employed to reduce the solution volume during the analysis of scattering from lossy dielectric objects. In a finite difference solution, they also can be utilized to avoid using small cells, made necessary by shorter wavelengths in conducting media throughout the solution volume.
